TABLE 1

Parameter vectors in murine atherosclerosis study (refer to Section 3, and Table 1 of the main paper). For each gene g the linear Anova model is defined by the $n \times k$ design matrix H of 0/1 of $1 \times k$ vector rows h_i^g for samples in the corresponding group, with additive effects $\beta_{g,\cdot}$ as we move through groups.

FIG 1. *Expression image of metagenes in the mice model analysis (refer to Section 5.4, and Figure 5, of the main paper). The metagenes are imaged for only those design groups for which there are significant gene expression changes (at the 0.99 probability level for at least one gene per group). This small number of metagene signatures across all design groups provide a massive dimension reduction of the expression data that conveys much of the information that globally characterises differences across genetic and environmental categories. In particular, these summaries and their numerical values characterise much of the discriminatory information across risk categories and define a “bar-code” of design states in a vastly reduced dimension relative to the original gene expression data.*

FIG 2. Heat map of mouse-model signatures projected on human aorta samples (refer to Section 8, and Figure 6, of the main paper). Colour coding red indicates higher levels of expression signatures, green indicates lower levels. This provides an overall visual assessment of the set of projected signatures. The key clinical measure “Lesion index” appears associated with higher signatures from the key risk groups (ApoE.Age, ApoE.Diet, ApoE.Age.Diet) across these human samples. In contrast, the SudanIV staining measure shows little or no relationship to the projected signatures.

TABLE OF GENES MOST HIGHLY SIGNIFICANT IN INTERSECTIONS OF RISK GROUPS

Table gives Affymetrix U133 human probeset names - homologues of probes on mouse array

The three risk groups are numbered as in the main text of the paper (see Table 1)

j=6 ApoE.Age group

j=8 ApoE.Diet group

j=13 ApoE.Age.Diet group
